- OIL & GAS Potential of Western Greece & MPOG® Applications

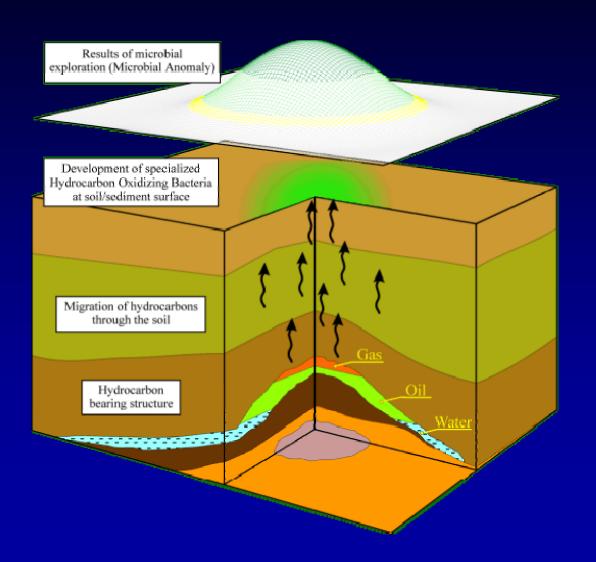

#### INTRODUCTION

- Microbial Prospection for Oil and Gas (MPOG®) is a <u>surface exploration</u> technology based on <u>detection of anomalies in microbial distribution</u> and <u>biochemical activity</u> in soil samples.
- Microbial Prospection is a <u>unique</u>, <u>stand-alone</u> and <u>inexpensive method</u>
   which has proved itself effective even in <u>complex geological settings</u>.
- The use of <u>specialised microbiological techniques</u> to detect the presence of various groups of <u>methane</u>-, <u>propane</u>- and <u>butane-oxidising</u> <u>micro organisms</u> can <u>reliably differentiate</u> between <u>prospective</u> and <u>non-prospective areas</u>, as well as <u>between oil and gas reservoirs!</u>
- In a 6,000 km² block, <u>17 onshore</u> and <u>offshore microbial anomalies</u>
   were identified, which subsequently were <u>confirmed by drilling!</u>

#### THE BASIS OF MPOG®

- The basis of MPOG<sup>®</sup> is that oil and gas fields emit a continuous stream of light hydrocarbon gases to the earth's surface.
- Specialized micro organisms, the <u>Hydrocarbon Oxidizing Bacteria</u>, use light hydrocarbon gases as their <u>only energy source</u>.
- Such micro organisms are able to utilize <u>extremely low concentrations</u>
   of <u>hydrocarbons</u> wherever there is a <u>continuous gas flow</u>, and are <u>only</u>
   found enriched under the <u>surface</u> above <u>hydrocarbon bearing structures</u>.
- The <u>exceptionally high adaptability</u> of bacteria to grow on most different nutrient sources and its <u>ubiquitous distribution</u> form the basis of MPOG<sup>®</sup> microbial prospecting method.

#### THE MPOG® PRINCIPLE

#### THE MPOG® METHODOLOGY

- No geological or seismic data are required to carry out MPOG<sup>®</sup> microbial prospecting.
- In green-field areas, the MPOG® sampling interval ranges from 500 m to a maximum of 1,000 m, depending on the expected reservoir size.
- The MPOG<sup>®</sup> method can give <u>principal evidence</u> on the occurrence of <u>hydrocarbon anomalies</u> in <u>very large exploration areas</u>!
- The <u>subsequent seismic</u> and <u>geological investigations</u> could thus be concentrated on the most favourable areas.
- In regions where <u>structural data</u> of the sub-surface <u>already exist</u>, the <u>MPOG</u> sampling interval can be reduced to <u>250-500m</u>, in order to create a <u>more detailed picture</u> of the <u>hydrocarbon anomalies</u>.

#### THE MPOG® METHODOLOGY (cont.)

- As a result, the <u>seismic structure maps</u> and <u>MPOG</u><sup>®</sup> <u>microbial</u> <u>anomalies maps</u>, which have been <u>drawn up independently from one another</u>, can be <u>compared and contrasted</u>.
- The MPOG<sup>®</sup> method is <u>particularly suitable</u> for the evaluation of the aerial extend of the field.
- The <u>higher the calculated measured units</u> (cell numbers and activity), the <u>more intense is the hydrocarbon supply</u> to the bacteria in the area under investigation, and therefore the <u>greater the probability of finding large hydrocarbon accumulations!</u>

#### MPOG® ADVANTAGES

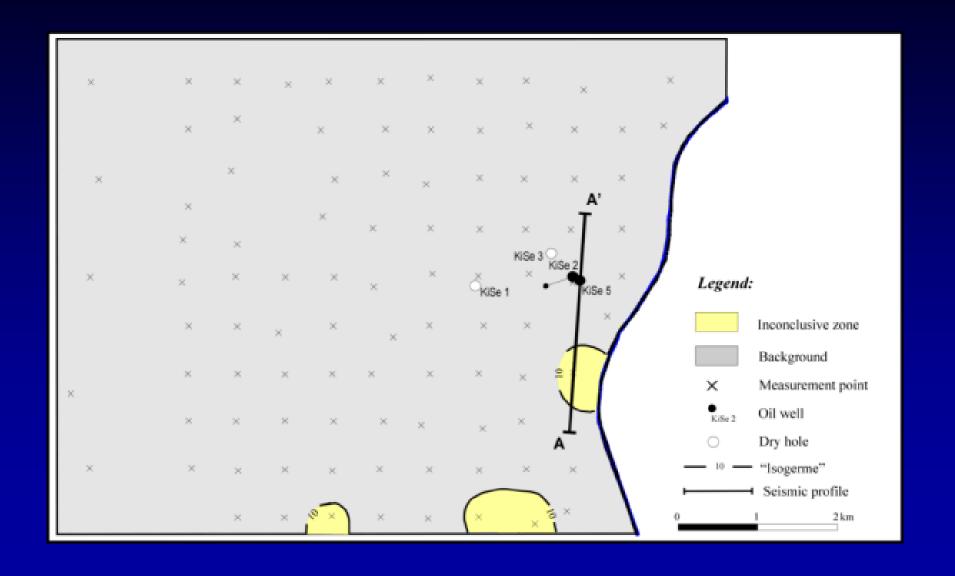

- MPOG<sup>®</sup> is applicable in both <u>onshore</u> and <u>offshore areas</u>.
- Sampling is <u>simple</u>, <u>cost effective</u> and <u>environmentally friendly</u>.
- The technique is <u>unaffected</u> by external <u>disturbance factors</u>.
- Reliable results are obtained even in geologically complex settings.
- The technique is <u>not influenced</u> by <u>fractures</u>, <u>overlying salt</u> or <u>other geological features</u>.
- Can establishing a <u>clear distinction</u> between <u>oil reservoirs</u>,
   gas reservoirs and <u>oil bearing structures with a gas cap</u>.
- Wherever <u>microbial evidence</u> establishes the presence of hydrocarbon anomalies, a <u>high yield well production rate is achieved (sweet spots)</u>.

#### MPOG® CASE STUDIES

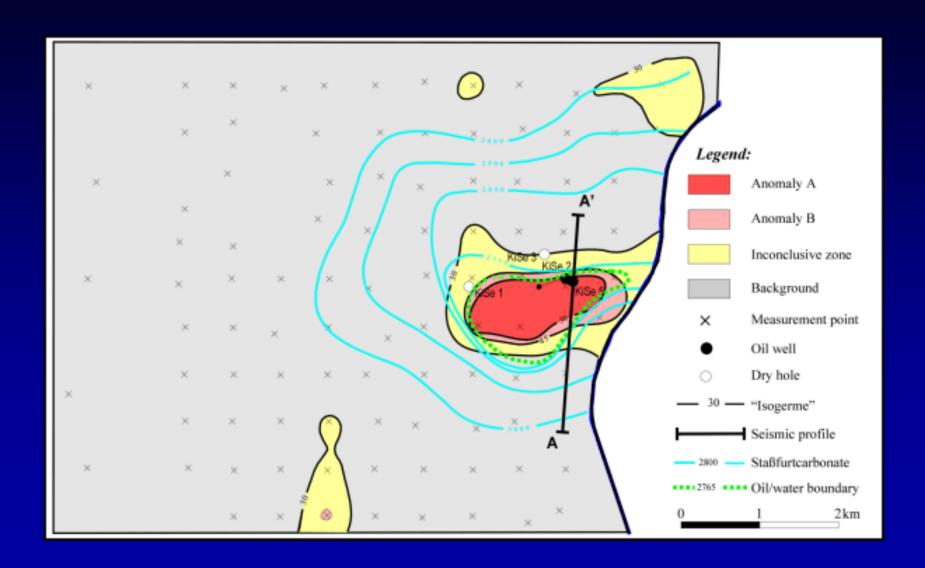

- The available case studies <u>compare</u> and <u>contrast</u> the results of the <u>MPOG</u><sup>®</sup> <u>microbial prospecting</u> with <u>seismic</u> and <u>geological data</u>.
- The MPOG<sup>®</sup> case studies to be presented were selected based on their <u>different geological settings</u> and <u>ALL were "blind tests"</u>.
- By separately identifying <u>methane</u> and <u>hydrocarbon-oxidizing bacteria</u>, it is possible to <u>differentiate</u> between <u>oil and gas reservoirs</u>, and <u>oil reservoirs with a gas cap!</u>
- Oil fields without a free gas cap have either no or small methane indications, but do have significant oil indications!
- Oil fields with a free gas cap create measurable methane anomalies and increased oil indications!

#### KIETZ HYDROCARBON-OXIDIZING BACTERIA RESULTS

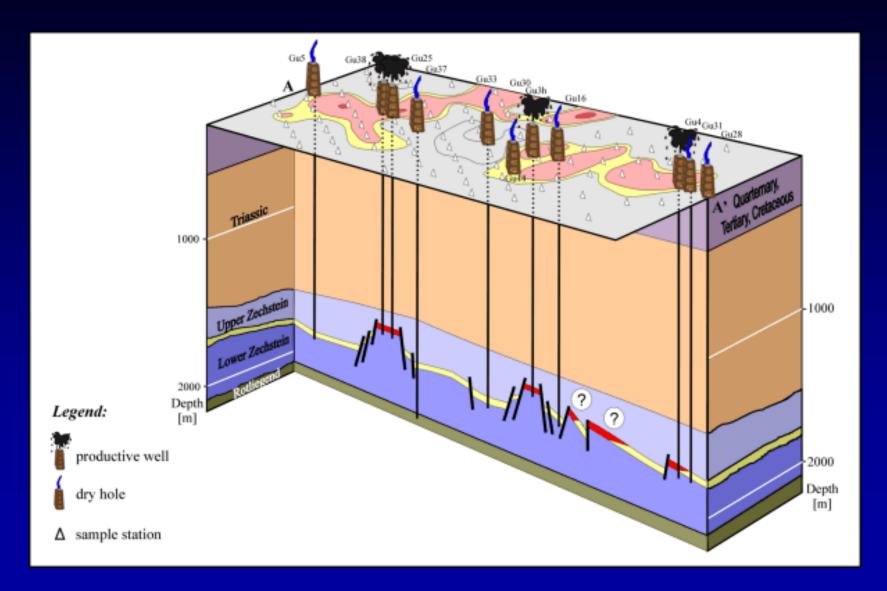

#### SPROETAU 3D GEOSEISMIC CROSS-SECTION

#### **GUBEN (ONSHORE)**

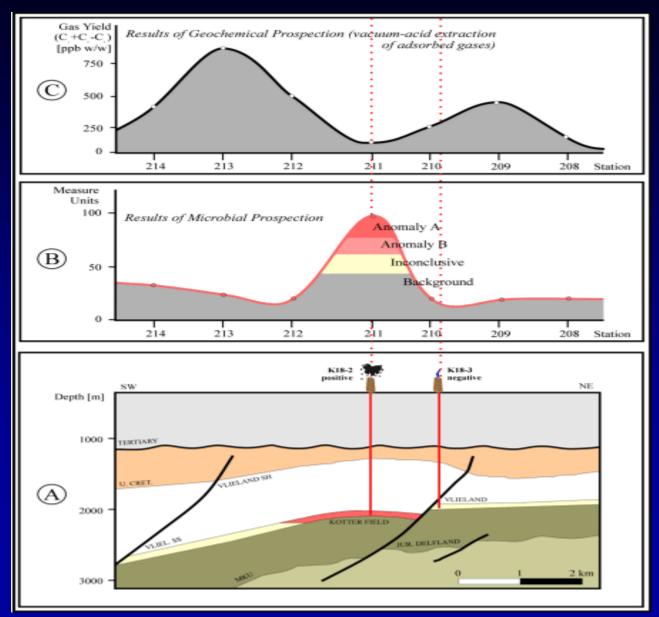

- In spite of <u>densely located 2D seismic profiles</u>, the exploration of the <u>small structure traps</u> was <u>very complicated</u>, reflected in the <u>large</u> <u>number of dry wells!</u>
- A total of <u>35 dry wells</u> were drilled on <u>detected geological traps</u>, which are mainly <u>located in areas without hydrocarbon indications</u> according to the MPOG<sup>®</sup> process!
- The <u>statistical evaluation</u> showed <u>8.3% oil indications</u> and <u>7.2% gas indications</u> from a <u>total of 278 investigated measuring points!</u>
